

# Compiling Distributed System Models into Implementations with PGo

Finn Hackett, Ivan Beschastnikh  
Renato Costa, Matthew Do

# Motivation

- Distributed systems are widely deployed
- Despite this fact, writing correct distributed systems is **hard**
  - ◆ Asynchronous network
  - ◆ Crashes
  - ◆ Network delays, partial failures...
- Systems deployed in production **often have bugs**

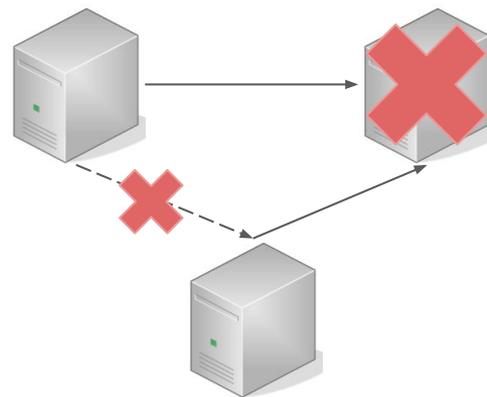

Cloud abstraction

Google's data center, Council Bluffs, IA  
<https://www.google.com/about/datacenters/gallery>

# Motivation

- Distributed systems are widely deployed
- Despite this fact, writing correct distributed systems is **hard**
  - ◆ Asynchronous network
  - ◆ Crashes
  - ◆ Network delays, partial failures...
- Systems deployed in production **often have bugs**

# Bugs in Distributed Systems

October 30, 2018 — Engineering, Featured, Product

## October 21 post-incident analysis

Jason Warner

### Degraded Performance

#### Google Compute Engine Incident #17003

New VMs are experiencing connectivity issues

Incident began at **2017-01-30 10:54** and ended at **2017-01-30 12:50** (all times are **US/Pacific**).

Feb 10, 2017 - GitLab 

### Postmortem of database outage of January 31

Postmortem on the database outage of January 31 2017 with the lessons we learned.

### Service Outage

### Data loss

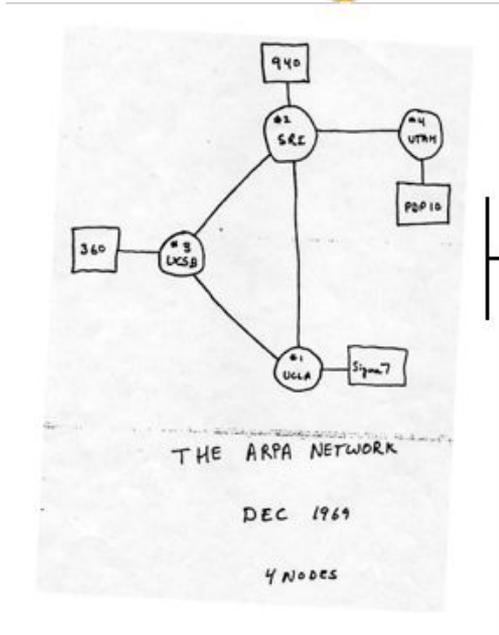

- [1] Mark Cavage. 2013. There's Just No Getting around It: You're Building a Distributed System. Queue 11, 4, Pages 30 (April 2013)
- [2] Fletcher Babb. Amazon's AWS DynamoDB Experiences Outage, Affecting Netflix, Reddit, Medium, and More. en-US. Sept. 2015
- [3] Shannon Vavra. Amazon outage cost S&P 500 companies \$150M. axios.com, Mar 3, 2017

# Protocol Descriptions Are **Not** Enough

- Distributed protocols typically have **edge cases**
  - ◆ Many of which may lack a **precise definition** of expected behavior
- Difficult to **correspond** final implementation with high-level protocol description, making **protocol changes harder**
- Production implementations resort to **ad-hoc error handling** [PODC'07, OSDI'14, SoCC'16, SOSP'19]

# One key problem for distributed systems

## Design

gap

## Implementation

# Related Work

- Using **proof assistants** to prove system properties
  - ◆ Verdi [PLDI'15], IronFleet [SOSP'15]
  - ◆ Require a lot of developer **effort** and **expertise**
- Model checking **implementations**
  - ◆ FlyMC [EuroSys'19], CMC [OSDI'02], MaceMC [NSDI'07], MODIST [NSDI'09]
  - ◆ **State-space explosion**: many states irrelevant to high-level properties
- Systematic **testing, tracing, and debugging**
  - ◆ P# [FAST'16], D<sup>3</sup>S [NSDI'08], Friday [NSDI'07], Dapper [TR'10]
  - ◆ **Incomplete**; requires runtime detection or extensive test harness

# Model Checking

- Verifies a **model** with respect to a **correctness specification**
- Specification can define **safety** and **liveness** requirements
- Produces a **counterexample** when a property is violated

# Model Checking a Bank Transfer

VARIABLES  $AliceSavings, BobSavings, Amount$

**Initial state:** both accounts have **positive** balance

$$Init \triangleq \begin{aligned} & \wedge AliceSavings \in Nat \\ & \wedge BobSavings \in Nat \\ & \wedge Amount \in Nat \end{aligned}$$

**Transfer**  $Amount$  between accounts

$$Transfer \triangleq \begin{aligned} & \wedge AliceSavings' = AliceSavings - Amount \\ & \wedge BobSavings' = BobSavings + Amount \end{aligned}$$

$$Spec \triangleq Init \wedge Transfer$$

**Property:** transfer should preserve positive balances

$$ValidBalances \triangleq AliceSavings > 0 \wedge BobSavings > 0$$

THEOREM  $Spec \Rightarrow ValidBalances$

# Visualizing an Error Trace

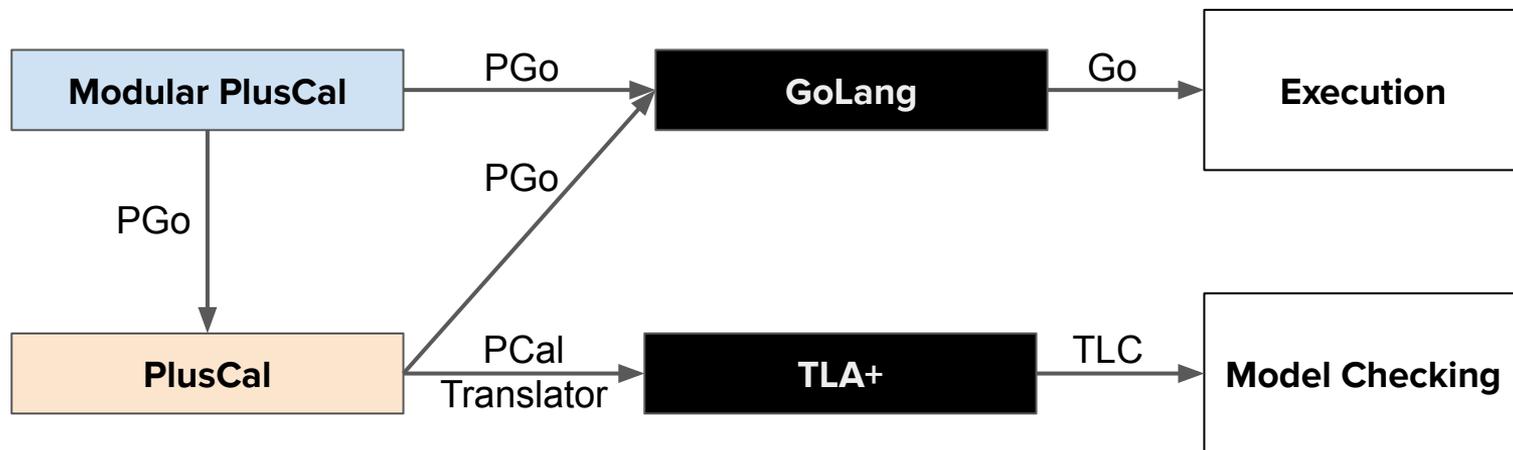

Name	Value
▼ ▲ <Initial predicate>	State (num = 1)
■ AliceSavings	1
■ Amount	2
■ BobSavings	1
▼ ▲ <Transfer line 10, col 13 to line 12, col 31 o	State (num = 2)
■ AliceSavings	-1
■ Amount	2
■ BobSavings	3

**Error:** our model does not check if Alice has **sufficient** funds!

## Overview of **PGo** and **Modular PlusCal**

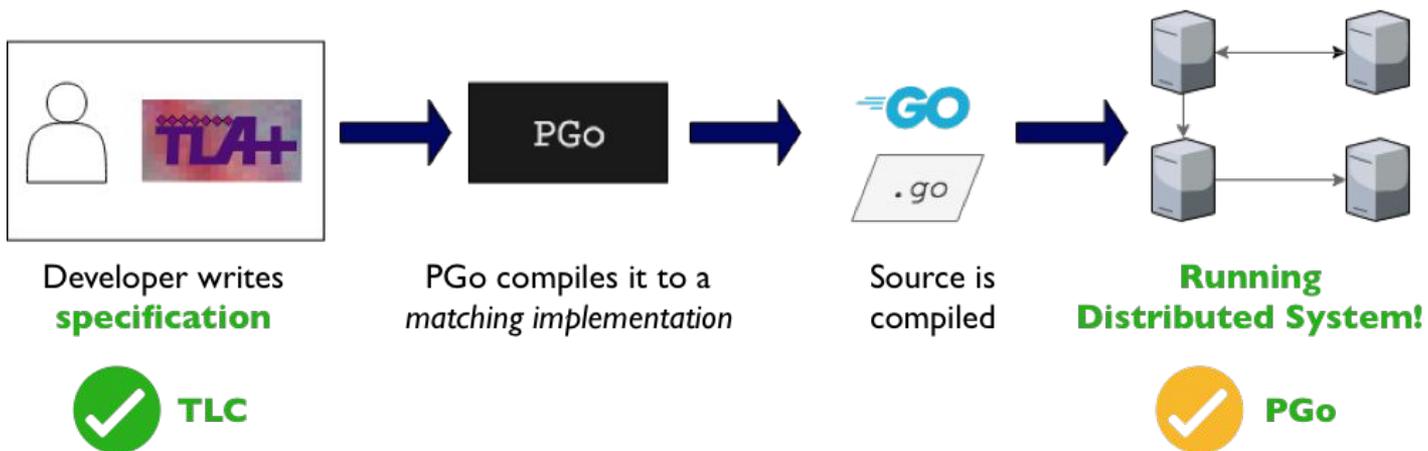

# PGo compiler toolchain

- PGo is a **compiler** from **models** in PlusCal/Modular PlusCal to **implementations** in Go
- Capable of generating **concurrent** and **distributed** systems from PlusCal specifications

# PGo workflow

Making building distributed systems **easier**

Transition from *design* (specification) to *implementation* is **automated**

# PGo trade-offs

## → Advantages

- ◆ Compatible with existing PlusCal/TLA+/TLC eco-system
- ◆ Mechanize the implementation = less dev work
- ◆ Maintain one definitive version of the system

## → Limitations

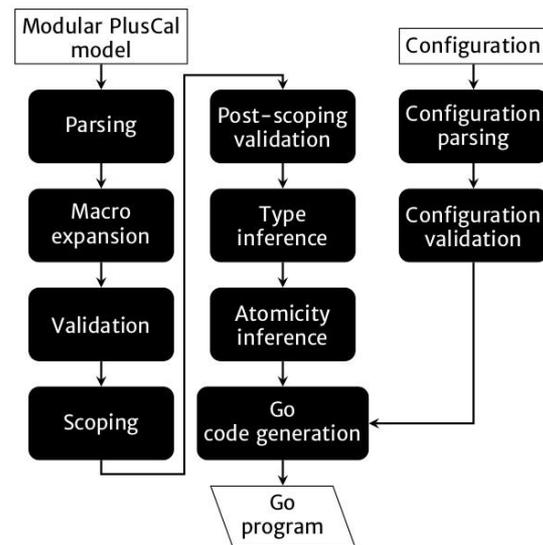

- ◆ **No free lunch: concrete details have to be provided somehow**
  - **Environment** is abstract: developer must **edit** generated source
  - **Bugs** can be introduced in this process
- ◆ **Software evolution**: unclear how to **reapply** the changes to model?

# In today's talk

- Focus on explaining ModularPlusCal (MPCal)
- Examples and demo
- Omit PGo compiler details:

## Compiling Modular PlusCal to Go with PGo

Pipeline

# How would you naively implement PlusCal code?

```
variables network = <<>>;  
...  
readMessage: \* blocking read from the network  
  await Len(network[self]) > 0;  
  msg := Head(network[self]);  
  network := [network EXCEPT ![self] = Tail(network[self])];
```

PlusCal

This algorithm is **not abstract enough**

```
readMessage: // blocking read from the network  
env.Lock("network")  
network := env.Get("network")  
if !(Len(network.Get(self)) > 0) {  
  env.Unlock("network")  
  goto readMessage  
}  
msg = Head(network.Get(self))  
env.Set("network", network.Update(self, Tail(network.Get(self))))  
env.Unlock("network")
```

Not a  
blocking  
network  
read

We **model** a  
network read, but  
this implementation  
**does not do that**

**Almost all** this code  
is for the **model  
checker**

Go

# Use macros?

```
variables network = <<>>;  
...  
readMessage:  
  NetworkRead(msg, self);
```

Semantics still rely  
on **global variables**

PlusCal

The **macro body** could  
be replaced by a  
**real-world  
implementation**

All processes will share the  
same **view of** and **access to**  
the **environment**

Network semantics  
become a **one-liner**

```
readMessage:  
msg := ReadNetwork(self)
```

Assumes one  
canonical network

Go

# Invent a new kind of macro: archetype

```
archetype AServer(ref network, ...)  
...  
readMessage:  
  msg := network[self];
```

Processes are **parameterised** by an **abstraction** over the environment

MPCa1

Any number of model checker and implementation behaviors can be defined elsewhere, since the environment is abstract

Complex network semantics can become a **variable read** or **write**

```
readMessage:  
msg := network.Read(self)
```

# Modular PlusCal: System vs Environment

- **Goal:** isolate system **definition** from abstractions of its **execution environment**
- Semantics of new primitives:
  - ◆ Archetypes can only interact with arguments passed to them
  - ◆ Archetype arguments encapsulate their environment and are called **resources**
  - ◆ Each resource can be **mapped** to an abstraction for model checking when archetypes are **instantiated**

# The Modular PlusCal Language

- ◆ **Archetypes**: define **API** to be used to interact with the concrete system
- ◆ **Mapping Macros**: allow definition of **abstractions**
- ◆ **Instances**: Configures abstract **environment** for model checking

```
variables network = <<>>; MPCa1

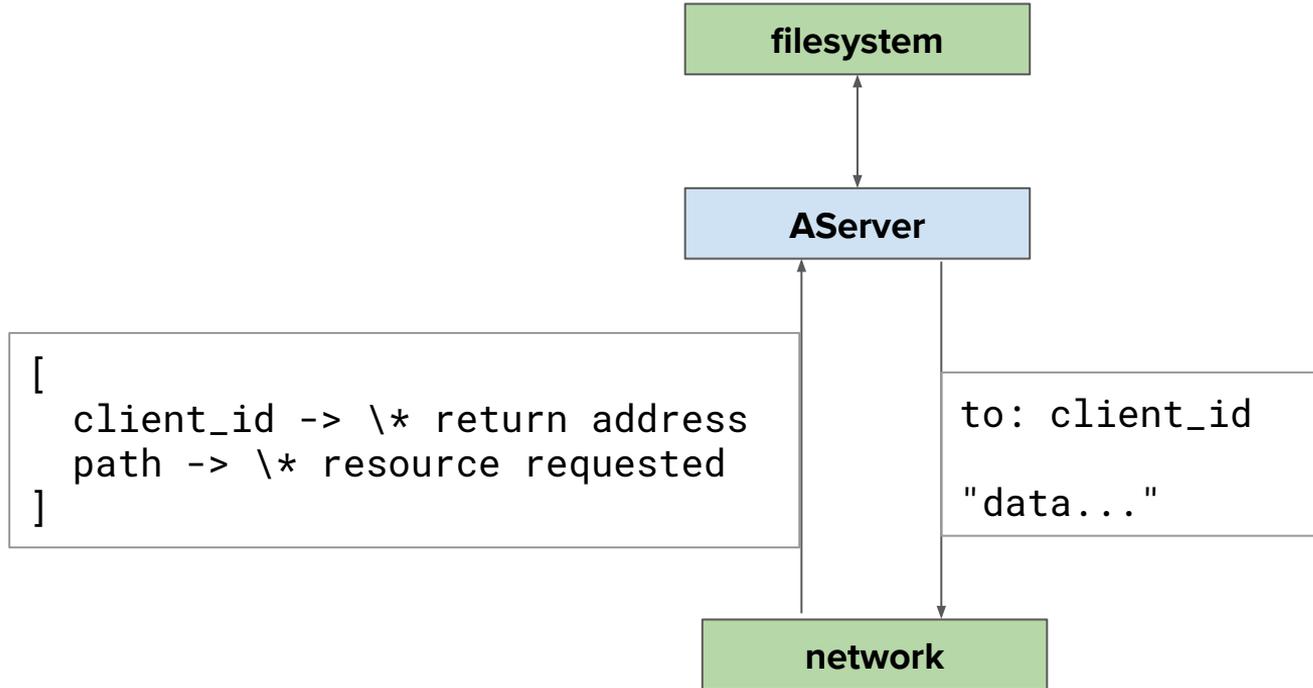

process (Server = 0) ==
  instance AServer(ref network, ...)
  mapping network[_] via TCPChannel
```

```
archetype AServer(ref network, ...)
...
readMessage:
  msg := network[self]; MPCa1
```

```
mapping macro TCPChannel{
  read {
    await Len($variable) > 0;
    with (msg = Head($variable)) {
      $variable := Tail($variable);
      yield msg;
    };
  }
  write {
    await Len($variable) < BUFFER_SIZE;
    yield Append($variable, $value);
  }
}
```

MPCa1

# Web server example

# Abstract Server with Buffered Network (PlusCal)

```
variables network = <<>>;
```

**Abstract environment:**  
network as **sequences**

```
process (Server = 0)
```

```
variable msg;
```

```
{
```

```
  readMessage:
```

```
    await Len(network[self]) > 0;
```

```
    msg := Head(network[self]);
```

```
    network := [network EXCEPT ![self] = Tail(network[self])];
```

Abstractly represents  
**reading** a message from  
the **network**

```
  sendPage:
```

```
    await Len(network[msg.client_id]) < BUFFER_SIZE;
```

```
    network := [network EXCEPT ![msg.client_id] = Append(network[msg.client_id], WEB_PAGE)];
```

```
    goto readMessage;
```

```
}
```

**Model checking**  
concern: only send  
messages if the buffer  
has space

Model website data as a  
**constant** called  
WEB\_PAGE

PlusCal

# Abstract Server with Buffered Network (MPCa1)

```
archetype AServer(ref network, file_system)
variable msg;
{
  readMessage:
    msg := network[self];

  sendPage:
    network[msg.client_id] := file_system[msg.path];
    goto readMessage;
}
```

Archetype has access to: a **network**, a **filesystem**

Interacting with the **network** becomes straightforward

Reading from the **filesystem** becomes clear, unlike just passing around a WEB\_PAGE **placeholder**

MPCa1

# Environment Abstractions: Buffered Network

What happens when a variable is read, transform the underlying value `$variable` and **yield** the result.

What happens when a variable is written, apply the new `$value` to the underlying `$variable` and **yield** the new underlying value.

```
mapping macro TCPChannel{
  read {
    await Len($variable) > 0;
    with (msg = Head($variable)) {
      $variable := Tail($variable);
      yield msg;
    };
  }
  write {
    await Len($variable) < BUFFER_SIZE;
    yield Append($variable, $value);
  }
}
```

MPCal

Abstract **blocking network read** semantics

Abstract **buffered network write** semantics

# Environment Abstractions: Filesystem Read

```
mapping macro WebPages {  
  read {  
    yield WEB_PAGE;  
  }  
  write {  
    assert(FALSE);  
    yield $value;  
  }  
}
```

Reading modeled  
**lossily** by returning a  
**constant**

Writing **not modeled**,  
so represented by  
**failure**

MPCa1

# Putting it All Together: Instances

**variables** network = <<>>;

Same **model checking**  
abstractions

**process** (Server = 0) == **instance** AServer(**ref** network, filesystem)

**mapping** network[\_] **via** TCPChannel

**mapping** filesystem[\_] **via** WebPages;

Server is an **instance**  
of AServer, with all the  
mapping macros and  
parameters **expanded**

**Function-mapping**  
syntax

MPCa1

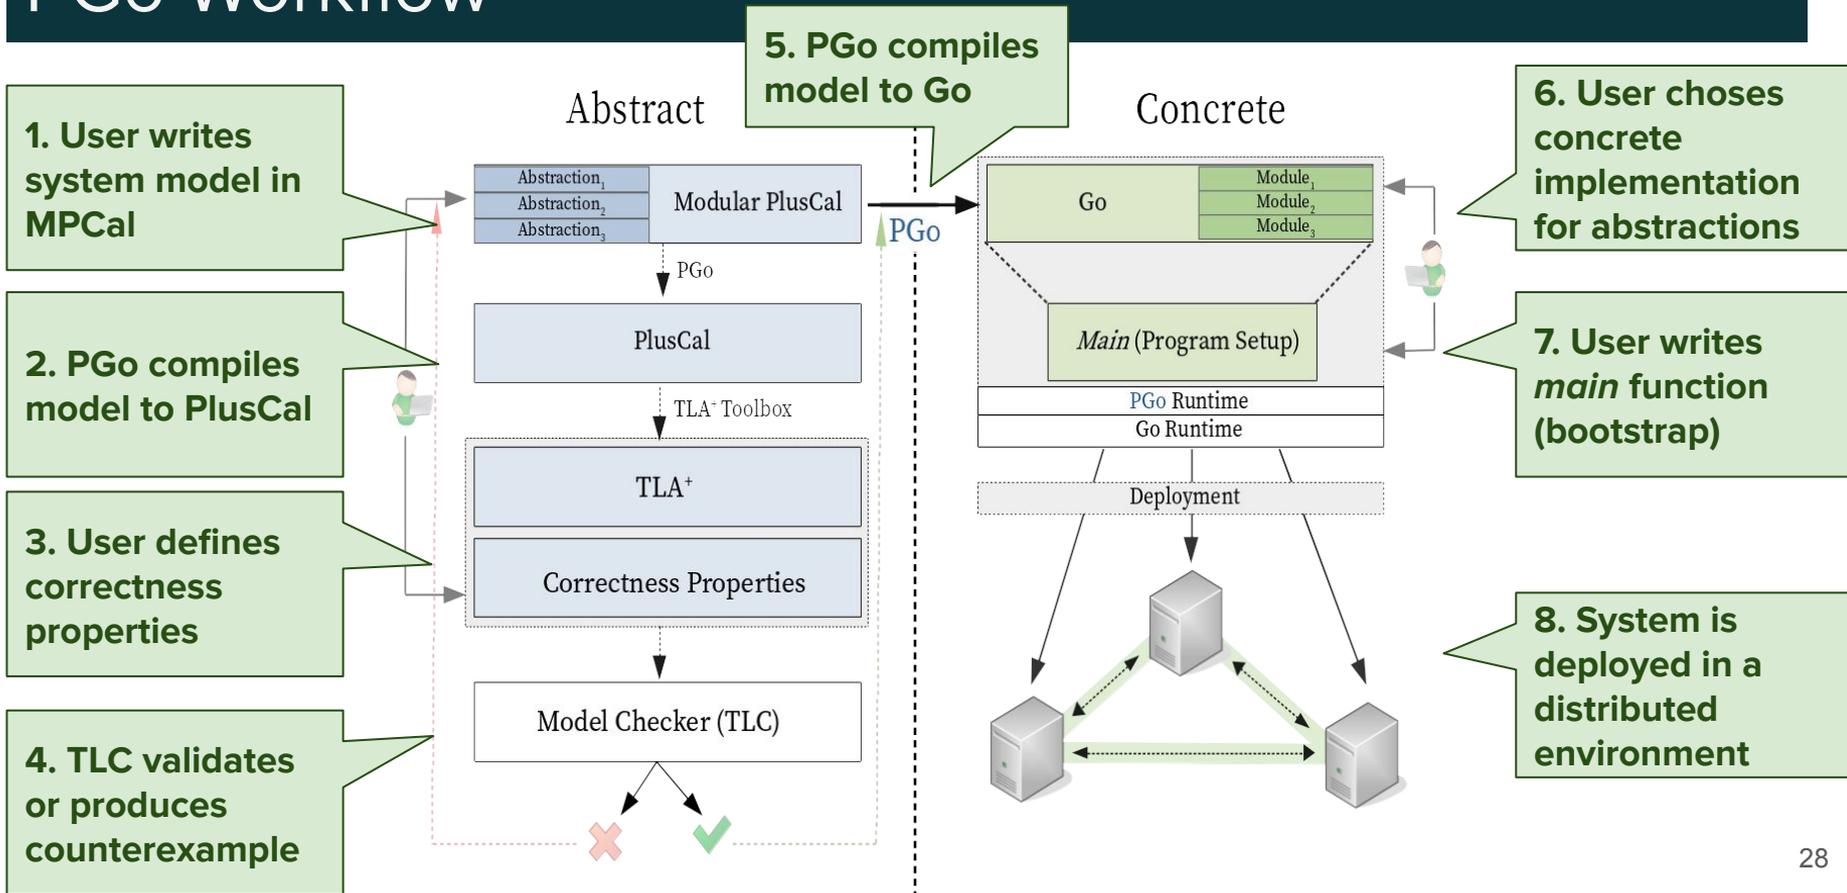

Mappings without the [\_] also exist:

mapping pipe **via** ... ;

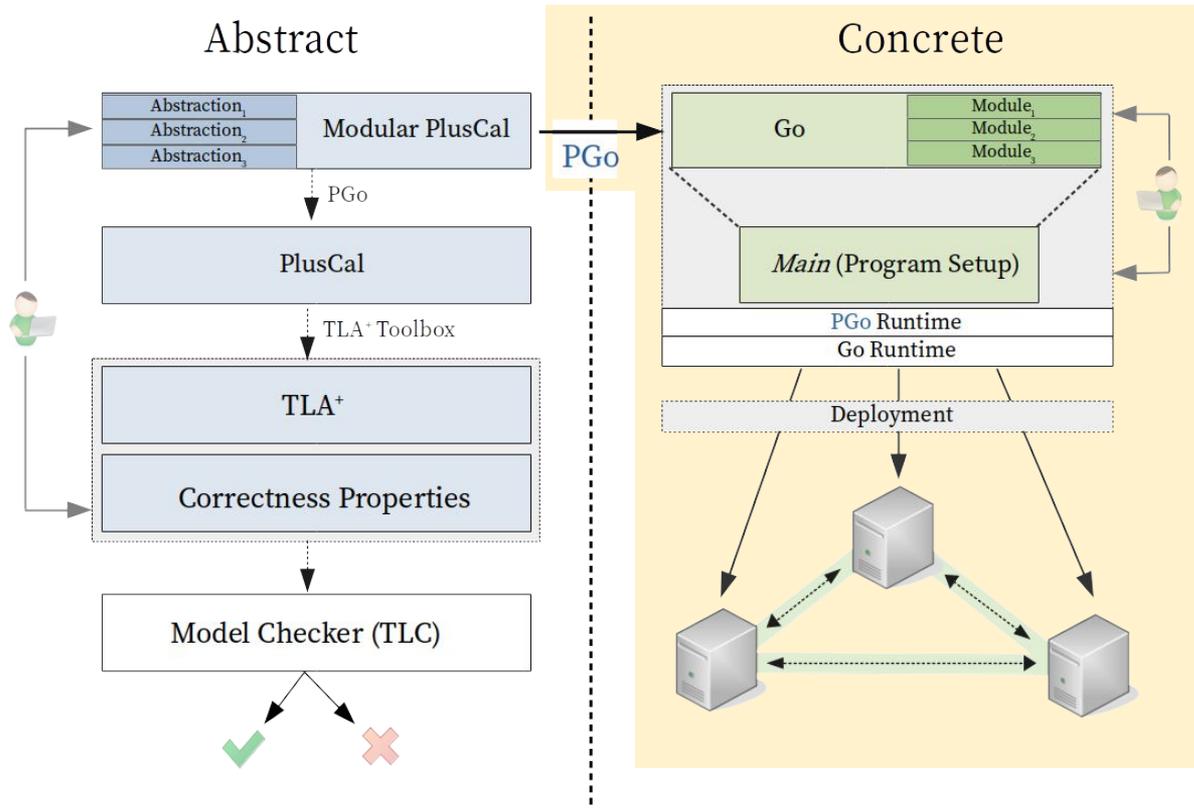

# Reviewing Source Languages

PlusCal	Modular PlusCal
<p><b>Abstract</b> environment; require <b>manual edits</b> in the generated implementation that can <b>introduce bugs</b></p>	<p>Abstractions are <b>isolated</b>: not included in archetypes. Behavior can be <b>preserved</b> if abstractions have <b>implementations</b> with <b>matching semantics</b></p>
<p>Protocol updates are <b>difficult</b>; developer needs to <b>reapply</b> manual changes</p>	<p>Protocol updates can be applied <b>any time</b>; generated code is <b>isolated from execution environment</b></p>

# PGo Workflow

# PGo Workflow

## **Compiling** Modular PlusCal to Go

# Defining our Objective

- **Goal:** every execution of the resulting system can be mapped to an accepted **behavior** of the spec
  - ◆ **Refinement**
- Environment modeled **abstractly** in Modular PlusCal needs an **implementation** in Go with **matching semantics**
- We need to understand how TLC explores behaviors **defined** by a model

# Coming Back to the Server Example

```
archetype AServer(ref network, file_system)
variable msg;
{
  readMessage:
    msg := network[self];

  sendPage:
    network[msg.client_id] :=
      file_system[msg.path];
    goto readMessage;
}
```

MPCal

```
archetype ALoadBalancer(ref network)
variables msg, next = 0;
{
  rcvMsg:
    msg := network[LoadBalancerId];
    assert(msg.message_type = GET_PAGE);

  sendServer:
    next := (next % NUM_SERVERS) + 1;
    mailboxes[next] := [
      message_id |-> next,
      client_id |-> msg.client_id,
      path |-> msg.path
    ];
    goto rcvMsg;
}
```

MPCal

# Behaviors in a Model

```
variables network = <<>>;
```

```
process (Server = 0) == instance AServer(ref network, filesystem)  
  mapping network[_] via TCPChannel  
  mapping filesystem[_] via WebPages;
```

```
process (LoadBalancer = 1) == instance ALoadBalancer(ref network)  
  mapping network[_] via TCPChannel;
```

MPCal

TLC explores all possible **interleavings** between two processes (instances)

# Interleavings between Processes

```
archetype ALoadBalancer(ref network)
variables msg, next = 0;
{
  rcvMsg:
  msg := network[LoadBalancerId];
  assert(msg.message_type = GET_PAGE);

  sendServer:
  next := (next % NUM_SERVERS) + 1;
  mailboxes[next] := [
    message_id |-> next,
    client_id |-> msg.client_id,
    path |-> msg.path
  ];
  goto rcvMsg;
}
```

MPCal

```
archetype AServer(ref network,
                  file_system)
variable msg;
{
  readMessage:
  msg := network[self];

  sendPage:
  network[msg.client_id] :=
    file_system[msg.path];
  goto readMessage;
}
```

MPCal

## Possible behaviors

```
rcvMsg
sendServer
readMessage
sendPage
```

```
readMessage
sendPage
rcvMsg
sendServer
```

```
rcvMsg
readMessage
sendServer
sendPage
```

**Labels define atomic steps in the model (or actions)**

## Impossible behavior

```
sendServer
rcvMsg
readMessage
sendPage
```

# Preserving Modular PlusCal Semantics in Go

- Trivial solution: **runtime scheduler** that chooses which step to run next
  - ◆ Prohibitively **expensive**, especially in a distributed system context
- **Goal**: achieve as much **concurrency** as possible across archetypes without changing behavior:
  - ◆ Exploit the fact that archetypes can only perform **externally visible** operations by interacting with its **resources** (parameters)
  - ◆ Achieve concurrency while preserving **atomicity** when it matters
  - ◆ Devise an algorithm to **safely** execute the statements in a step

# Reasoning about Concurrency (part 1)

→ Steps that **do not use** any resource are **safe** to be executed **concurrently** with other steps

- ◆ Their effects are “**invisible**”
- ◆ **Equivalent** to some **sequential** execution explored by TLC

```
archetype AServer(ref network,  
                  file_system)  
  
variable msg;  
{  
  start:  
    print “Waiting for message”;  
  
  readMessage:  
    msg := network[self];  
  
  sendPage:  
    network[msg.client_id] :=  
      file_system[msg.path];  
    goto readMessage;  
}
```

MPCal

# Reasoning about Concurrency (part 2)

```
archetype ALoadBalancer(ref network)
variables msg, next = 0;
{
  rcvMsg:
  msg := network[LoadBalancerId];
  assert(msg.message_type = GET_PAGE);

  sendServer:
  next := (next % NUM_SERVERS) + 1;
  network[next] := [
    message_id |-> next,
    client_id |-> msg.client_id,
    path |-> msg.path
  ];
  goto rcvMsg;
}
```

MPCa1

```
archetype AServer(ref network,
                  file_system)
variable msg;
{
  start:
  print "Waiting for message";
  readMessage:
  msg := network[self];
  sendPage:
  network[msg.client_id] := file_system[msg.path];
  goto readMessage;
}
```

MPCa1

- Steps that use the the **same resource** (environment) **may not** be safe to run concurrently
- ◆ Let **implementation** dictate **safety** of concurrent execution
  - ◆ If **exclusive access** is needed (such as in our log), **locks** can be used

# Executing an Atomic Step in Go

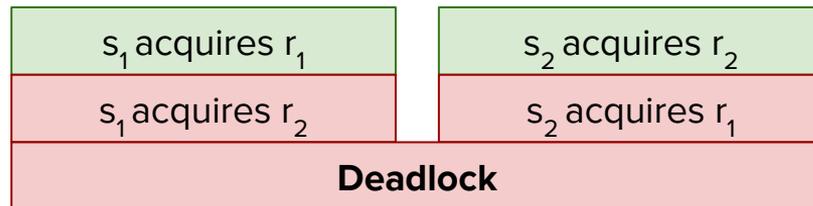

- We generate a **Go function** for each **archetype** instantiated in the model
  - ◆ Steps in an archetype may be executed **concurrently** with steps from other archetypes
- Overview of the execution model of a **single step**:
  - ◆ **Acquire** all resources used in the step
  - ◆ Execute all **statements** in order
  - ◆ **Release** all resources at the end
- Is this always safe?

# Deadlocks!

- Steps  $s_1$  and  $s_2$  interact with resources  $r_1$  and  $r_2$ , but in different orders
- Suppose also that they both require **exclusive access**
- **Deadlock** becomes possible

```
s1:  
  if (r1 > 0) {  
    r2 := 0;  
  }  
MPCal
```

```
s2:  
  if (r2 > 0) {  
    r1 := 0;  
  }  
MPCal
```

# Updating our Execution Model

→ Resources are acquired in **consistent order**

◆ Either  $\langle r_1, r_2 \rangle$  or  $\langle r_2, r_1 \rangle$ ,  
**always**

→ Updated execution model:

- ◆ Acquire all resources used in the step, **in consistent order**
- ◆ Execute all statements in order
- ◆ Release all resources at the end

```
s1:  
  if (r1 > 0) {  
    r2 := 0;  
  }  
MPCa1
```

```
s2:  
  if (r2 > 0) {  
    r1 := 0;  
  }  
MPCa1
```

# Reasoning about the Execution Model

- We offer a **reduction argument** about the safety of the execution model
- Take any two labels. There are three cases to consider:
  - ◆ One of the labels **does not use any resource**: equivalent to sequential execution
  - ◆ Labels use **disjoint** sets of resources: equivalent to sequential execution (steps interact with **different parts** of the environment)
  - ◆ Labels use **overlapping** sets of resources: if resources require **exclusive access**, they should implement that behavior when being **acquired**.

# Resources Mapped as Functions

```
process (Server = 0) == instance AServer(ref network,  
                                       filesystem)  
mapping filesystem[_] via WebPages  
MPCal
```

```
sendPage:  
  network[msg.client_id] :=  
    file_system[msg.path];  
goto readMessage;  
MPCal
```

- Resources can be **mapped as functions**
- **Entire function applications** is seen as the resource
- **Challenge**: statically analysing MPCal model is **no longer sufficient** to determine resources used in a step

## Solution

- Resources mapped as functions are acquired **in the statement they are used**
- Drawback: they **cannot** be acquired in consistent order
- Instead, we allow actions to be **restarted** during a potential deadlock

# Executing a Modular PlusCal step (action) in Go

## Algorithm 1: Action Execution

```
actionCompleted = FALSE;  
while  $\neg$  actionCompleted do
```

```
  Acquire all resources not mapped as functions in consistent order;  
  ... action statements ...;
```

```
  /* A resource mapped as function is required at  
     this point */
```

```
  error = Acquire(resourceMappedAsFunction);
```

```
  if error  $\neq$  NULL then
```

```
    Abort all resources acquired so far;
```

```
    if ShouldRetry(err) then
```

```
      continue;
```

```
    end
```

```
  return error
```

```
end
```

```
... more action statements ...;
```

```
/* End of action
```

```
Release all acquired resources;
```

```
actionCompleted = TRUE;
```

```
end
```

Main loop: only exit when the step is **complete**

Execute the **statements** defined in the **model**

If it cannot be acquired (potential **deadlock**), **restart from scratch**

Resources **not mapped as functions** acquired in **consistent order** as described

Resource **mapped as function** is used in a statement

When **all** statements are executed, make environment changes **externally visible**

# Linking Abstractions and Concrete Implementations

- PGo is not aware of the **concrete representation** of abstract resources passed to archetypes
- Instead, we define a **contract** that valid implementations must follow
  - ◆ If implementation matches abstraction, code generated by PGo **does not need to be manually edited**

# Environment Implementations: Requirements

- What is needed from these implementations?
  - ◆ A way to “**acquire**” them before use (enforcing **exclusive access** if necessary)
  - ◆ **Interacting** with the environment (reading, writing)
  - ◆ Making environment changes **visible** at the end of the atomic step
  - ◆ **Aborting** local interaction if step needs to be **restarted**

# Archetype Resources API (in Go)

```
type ArchetypeResource interface {  
    Acquire(ResourceAccess) error  
    Read() (interface{}, error)  
    Write(interface{}) error  
    Release() error  
    Abort() error  
    Less(ArchetypeResource) error  
}
```

Called **before** the resource is read or written

**Discards** interactions when actions need to be **restarted**

Only call that can make **externally visible** effects

Allow resources to be **comparable** (enforcing **consistent order**)

Go

# Handling Errors

- API functions implemented by resources may return **errors**
- Errors are used for **two purposes** during execution:
  - ◆ To flag unrecoverable **environment errors**
  - ◆ To request that an action be **restarted** (e.g., potential deadlock)

Environment Errors	Restart Request
<b>I/O error</b> reading or writing to a file or socket; network operation <b>timeout</b>	Attempt to read a socket when <b>no message is available</b> ; attempting to <b>lock shared data</b> that is already locked

## DEMO

Compiling and Running `load_balancer.tla`

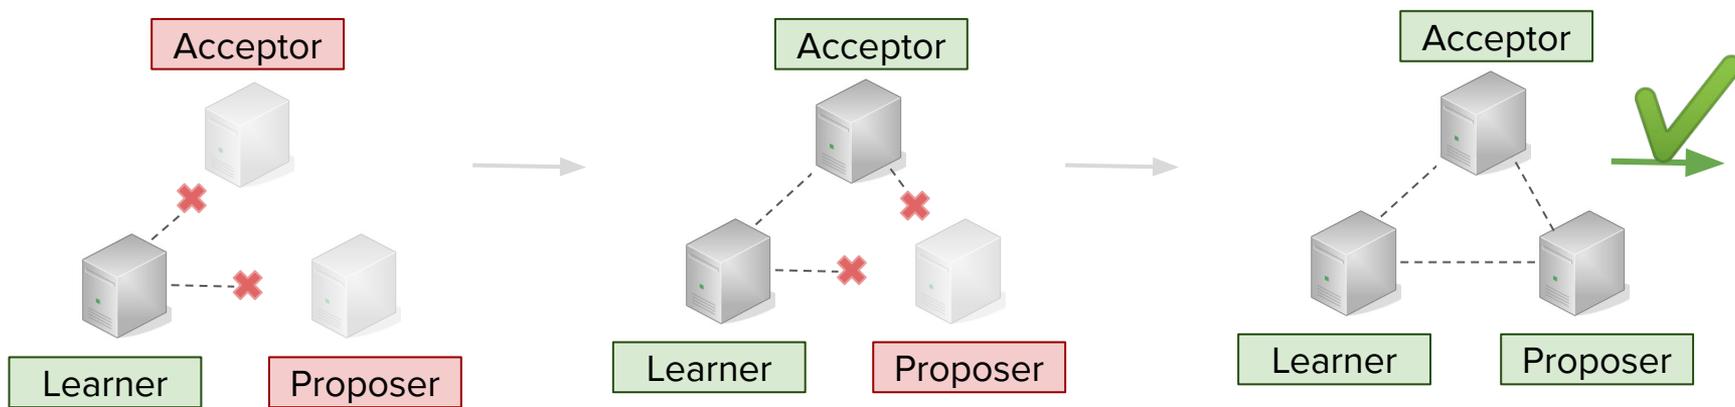

# Distributed **Runtime**

# Execution Runtime

- **Goal:** reduce the **burden** on developers by providing resources often used in distributed systems
  - ◆ **Scheduling** setup
  - ◆ **Network** communication
  - ◆ **Global state**
  - ◆ Others: file system, time, shared resources, etc...

# Synchronized Start

- Allows processes (that may run on **different nodes** when deployed) to **coordinate** when they start execution
  - ◆ TLA<sup>+</sup> **weak fairness**
- Developer can use it to enforce a **distributed barrier**

# Distributed Global State

- Provides the abstraction of **shared state** in a distributed system
- Exposed as an archetype **resource** implementation
  - ◆ Makes it easier to **migrate** PlusCal spec to Modular PlusCal
- Data is stored **across all nodes** in the system
  - ◆ Objects are **owned** by only one at a time, but can **move** over time
  - ◆ (Many exciting future work directions hide here :-)

# Distributed Global State: Data Store

Name	Value	Owner
<i>counter</i>	42	P <sub>1</sub>
<i>queue</i>	nil	P <sub>3</sub>
<i>history</i>	nil	P <sub>2</sub>

Node has value for data it **owns**

Name	Value	Owner
<i>counter</i>	nil	P <sub>3</sub>
<i>queue</i>	nil	P <sub>3</sub>
<i>history</i>	["e1", "e2"]	P <sub>2</sub>

No state kept if **not owned**

Name	Value	Owner
<i>counter</i>	nil	P <sub>1</sub>
<i>queue</i>	["j1", "j2"]	P <sub>3</sub>
<i>history</i>	nil	P <sub>1</sub>

Ownership may be **outdated**

## Evaluation

- PGo is 25K LOC (compiler) and 3K (runtime)
- Able to compile concurrent and distributed systems
- Supports different dist. state strategies

# Evaluation

- Is the implementation **sufficiently robust** to support the compilation of **complex specifications**?
- Do systems compiled by PGo have **behavior** that is **defined** by the specification?
- What is the **performance** of systems compiled by PGo, and how does it **compare** with similar, **handwritten** implementations?

# A partial set of specs that we wrote

- Load Balancer model:
  - ◆ Defines interaction of a **load balancer**, multiple **servers** and multiple **clients**. Implementations interact with the **file system**
- Replicated Key-Value Store:
  - ◆ **Serializable** key-value consistency semantics
  - ◆ Replicated state machines using **Lamport logical locks** to determine **ordering** and **stability**\*
  - ◆ An assignment at UBC in Winter 2019
- **Raft** and **Paxos** models; no eval for these yet

\* as described in *Implementing Fault-Tolerant Services Using the State Machine Approach: a Tutorial*

# MPCal and Go LOC

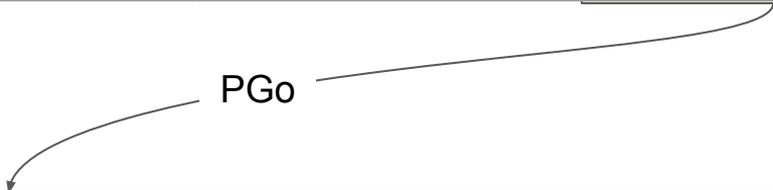

<b>Specification</b>	<b>Archetypes</b>	<b>Mapping macros</b>	<b>MPCal LOC</b>
Load balancer	3	2	79
Replicated KV	5	6	291

<b>Implementation</b>	<b>PGo-gen Go LOC</b>	<b>Manual Go LOC</b>	<b>Total Go LOC</b>
Load balancer	494	85	579
Replicated KV	3,395	234	3,629

# MPCal and Go LOC

Specification	Archetypes	Mapping macros	MPCal LOC
Load balancer	3	2	79
Replicated KV	5	6	291

PGo

Implementation	PGo-gen Go LOC	Manual Go LOC	Total Go LOC
Load balancer	494	85	579
Replicated KV	3,395	234	3,629

# Semantic Equivalence

- **Proof** that resulting system is **semantically equivalent** to original model is future work (certified compilation)
- Tested both systems
  - ◆ Load balancer: different **numbers of clients/servers**; files of different **sizes**; verified result was **received by client** as expected
  - ◆ Replicated Key-Value Store: Different **numbers of clients/replicas**; keys and values as **random bytes** of configurable length; clients issue request **sequentially** or **concurrently**; at the end: all replicas are **consistent**.
  - ◆ **All tested student solutions had bugs** when the same test suite was used!

# Performance Comparison

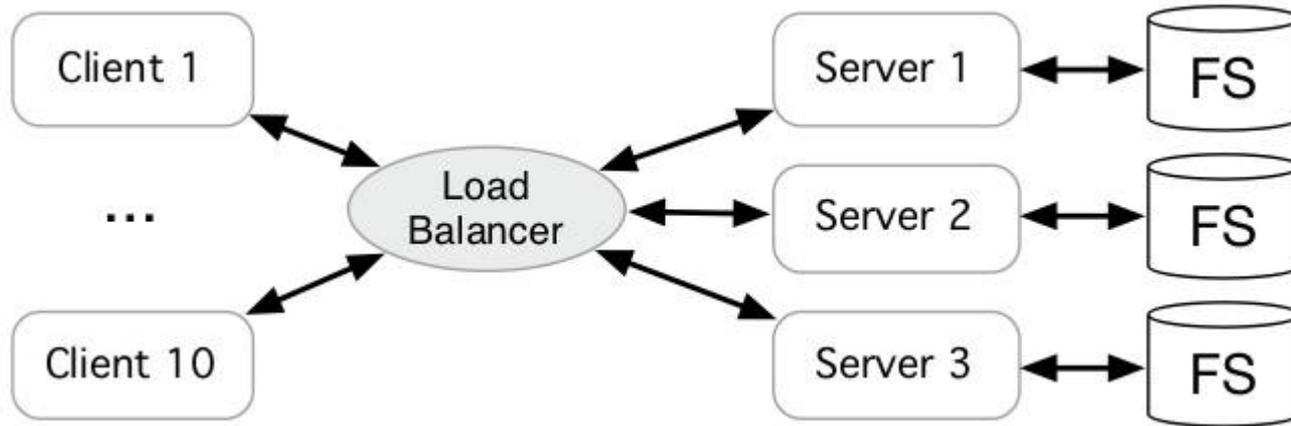

- Comparison with **handwritten** versions of the load balancer and replicated key-value store

Implementation	PGo version (gen)	Manual version
Load balancer	579 (494)	156
Replicated KV	3,629 (3,395)	406

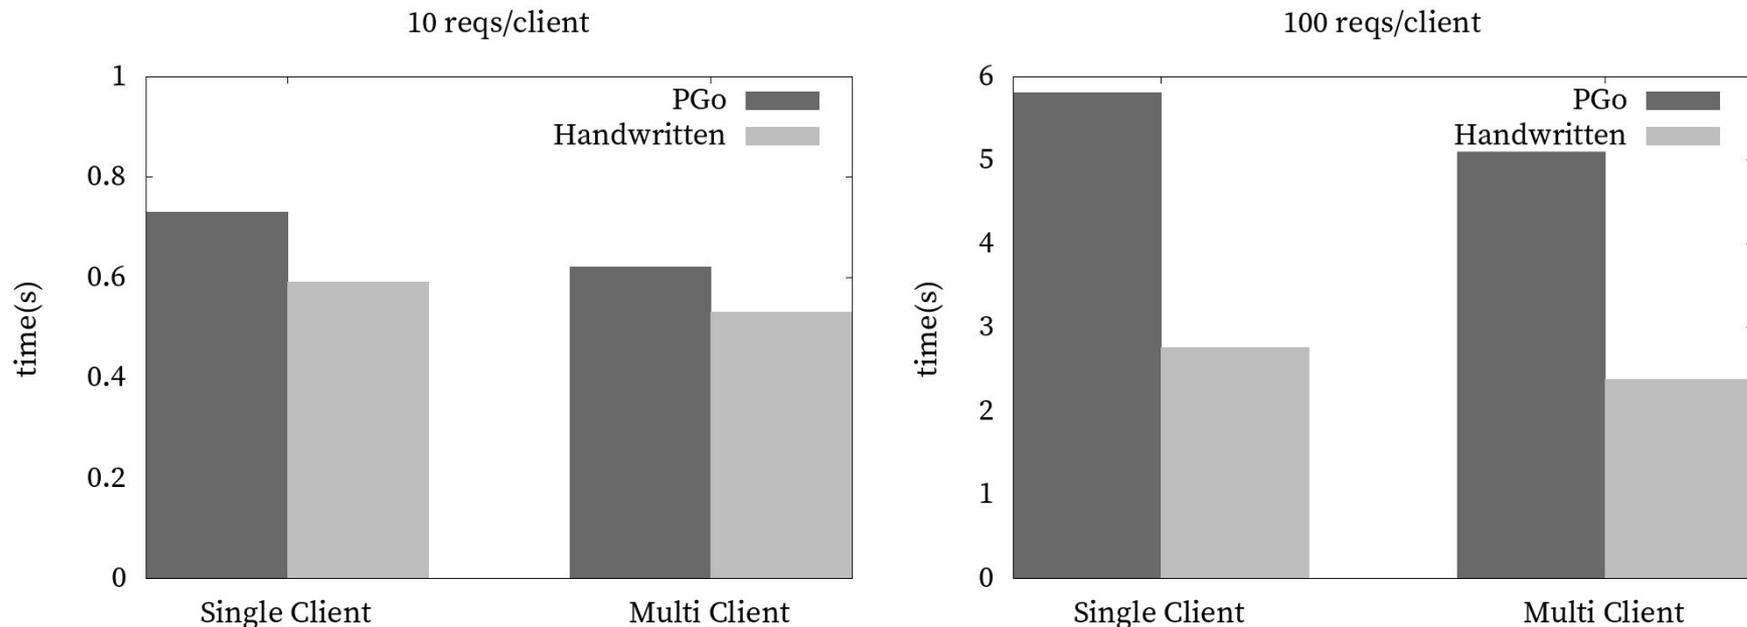

5-8x LOC  
increase

- Experimental setup: all processes running on the **same node**, focus on **runtime** overhead

# Load Balancer setup

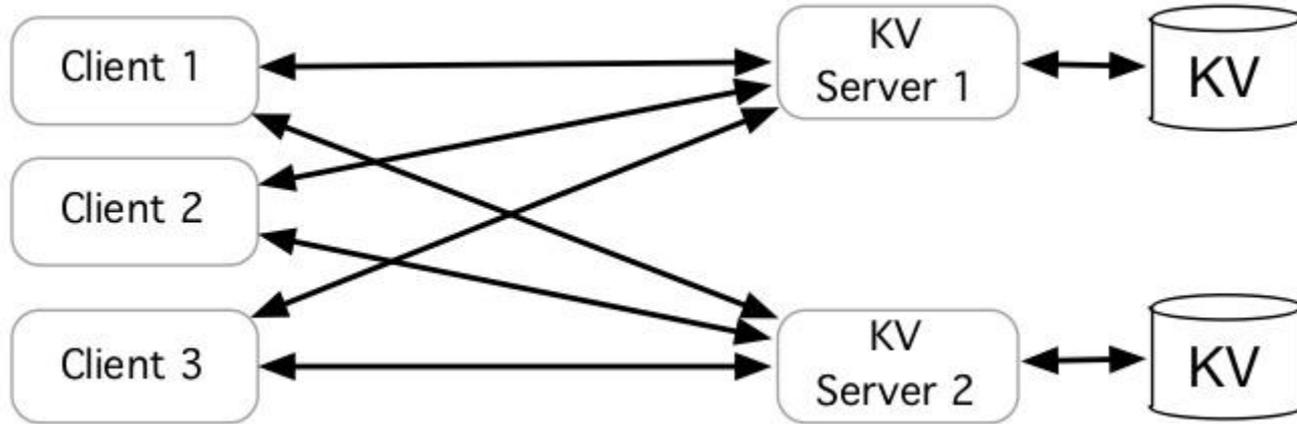

# Performance results: Load Balancer

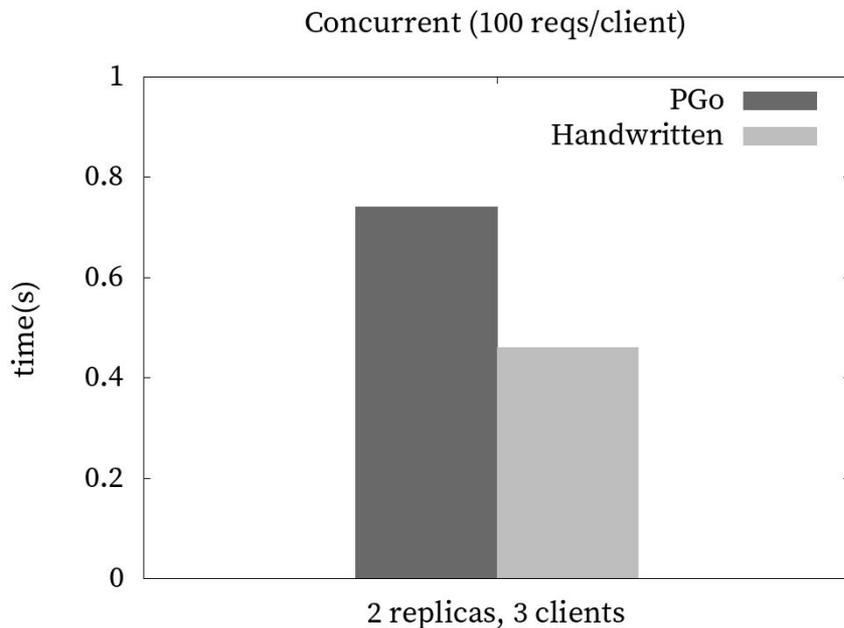

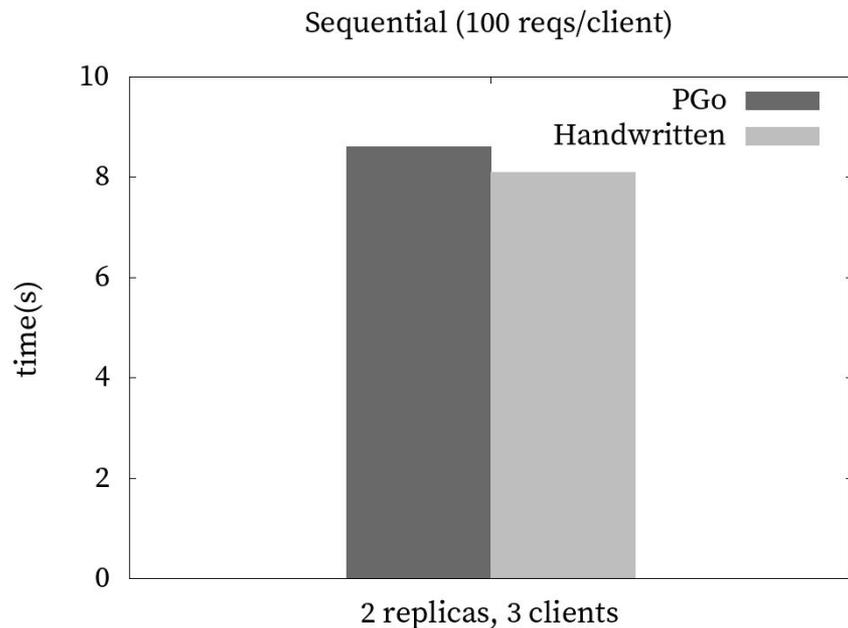

Load balancer with one or multiple clients performing 10 (left) or 100 (right) requests per client.

# Replicated Key-Value Store setup

# Performance results: Replicated Key-Value Store

Time it takes for three clients to perform 100 operations, first sequentially (left) and then concurrently (right).

## Discussion

# Discussion: Limitations and Future Work

- Compilation is **not verified**
  - ◆ Trusted: **TLC** model checker, **PGo** compiler and runtime, **Java** compiler and runtime, **Go** compiler and runtime, **operating system**.
- **Fault tolerance** needs further work
  - ◆ Limited ways to deal with failures; lack of **language support**
- **Performance** can be improved
  - ◆ **Restarting** actions can be expensive
- **Fairness** is not guaranteed
  - ◆ Go favors performance over fairness; **mismatch** with original model

# PGo take-aways

- Described how PGo leverages **separation** between **system** and **abstractions** to generate **correct** distributed systems
- More work is necessary to make it a viable option for the development of **production-quality** distributed systems
